The Importance of Drug Interactions

Each year in the U.S. there are innumerable adverse drug reactions, broadly defined as any unexpected, unintended, undesired, or excessive response to a medicine. Such reactions may require discontinuing or changing medication therapy. Furthermore, greater than 2 million of those are serious reactions resulting in hospitalization and/or permanent disability, and there are more than 100,000 deaths annually attributed to reactions involving prescribed medications (Cohen 1999; Wilkinson 2005).

Three-fourths of those adverse reactions relate to drug interactions, which occur when the amount or action of a drug in the body is altered – usually increased or decreased – by the presence of another drug or multiple drugs (Bochner 2000; Levy et al. 2000; Piscitelli and Rodvold 2001). Avoiding these can be difficult, since the number of potential interactions among diverse drugs used in clinical practice can be overwhelming; more than 2,000 such interactions have been described in the literature and new cases appear monthly (Levy et al. 2000). As the tables in this document indicate, there are more than 100 substances – medications, illicit drugs, OTC products, etc. – that can interact in some fashion to affect a patient’s response to methadone.

Pharmacotherapy is increasingly complicated by the introduction of new drugs and the use of multidrug regimens – called “polypharmacy” – for acute or chronic disease, which can result in clinically important drug interactions. While multiple drugs often are necessary for treating complex or resistant conditions, side effects of the drugs themselves may induce disease symptoms rather than any pathological processes (Farrell et al. 2003). This is of vital importance for patients in methadone maintenance treatment (MMT) programs, since these individuals often have co-occurring physical and mental disorders requiring multiple medications.

During clinical use in the maintenance treatment of opioid addiction, spanning more than 40 years, oral methadone has proven to be a well-tolerated medication with minimal adverse reactions when prescribed in appropriate doses and taken daily as a component of MMT (Kreek 1973; Novick et al. 1993). However, there are potential methadone-drug interactions – involving prescribed medications, illicit drugs, OTC products, and other substances – which sometimes can be difficult to predict. Such interactions may be potentially harmful and/or can lead to treatment failures (Harrington et al. 1999; Levy et al. 2000).
**Metabolic Basics**

Most drugs are foreign to the human body and are broken down (metabolized) by chemical reactions into molecules that can be more easily eliminated (Flexner and Piscitelli 2000). A primary metabolic pathway involves the actions of proteins, called cytochrome P450 (CYP450) enzymes, that facilitate those chemical reactions. These enzymes evolved as a protective mechanism more than 3 billion years ago to cope with a growing number of naturally occurring environmental chemicals and toxins (Hardman et al. 1996; Richelson 1997).

There are more than 28 CYP enzymes encoded by 57 different human genes (Flexner and Piscitelli 2000; Shannon 1997; Wilkinson 2005). Each is designated by a combination of numbers and letters: for example, 3A4 and 2B6 which are important in methadone metabolism. CYP enzymes reside mainly in the liver, but also are present in other organs. Substances that interact with the CYP450 system usually do so in one of three ways: 1) by acting as a substrate, 2) through inhibition, or 3) through induction.

- A **substrate** is any drug metabolized by one or more CYP enzymes, and more than half of all medications that undergo metabolism are CYP3A4 substrates (Piscitelli and Rodvold, 2001).

- Some drugs are **inhibitors** of specific CYP enzymes and thereby slow the metabolism of drugs that are substrates for those particular enzymes, which may result in excessively high drug levels and related toxic effects (Levy et al. 2000).

- Other drugs are **inducers**; they boost the activity of specific CYP enzymes resulting in more rapid metabolism of substrate drugs, which may result in lower than expected levels of the substrate drugs (Flexner and Piscitelli 2000).

A drug can at the same time be a substrate for and induce or inhibit one or more CYP enzymes. Co-administered drugs that merely share the same metabolic pathway – that is, are substrates for the same CYP enzymes – may compete with each other. The “winning drug” could garner more enzyme activity, thus diminishing metabolism of the other drug and intensifying its effects (Hardman et al. 1996). Readers may wish to consult current sources listing drugs that are CYP450-enzyme substrates, inducers, or inhibitors; such as at [http://drug-interactions.com](http://drug-interactions.com) (Flockhart 2003).

**Methadone Metabolism**

Methadone is usually readily absorbed, with about 80% of the administered dose passing into the bloodstream during stabilized MMT and the remainder metabolized in the GI tract and liver; although, for reasons described below, absorption can range from 35% to 100% (Eap et al. 2002, Moolchan et al. 2001). The three formulations of oral methadone used in MMT – solid tablets, dispersible tablets, and liquid concentrate – have been demonstrated as intrinsically equal in terms of their absorption and metabolism (Gourevitch et al. 1999); however, patient reactions to each formulation may vary, possibly due to psychosomatic factors in some cases.

The most important enzymes in methadone metabolism are CYP3A4 and CYP2B6. Secondarily CYP2D6 appears to have a role, and CYP1A2 may possibly be involved (see Table).
CYP3A4, the most abundant metabolic enzyme in the body, can vary 30-fold between individuals in terms of its presence and activity in the liver (Eap et al. 2002; Leavitt et al. 2000). This enzyme also is found in the gastrointestinal tract, so methadone metabolism actually can begin before the drug enters the circulatory system (Hardman et al. 1996). The amount of this enzyme in the intestine can vary up to 11-fold, partially accounting for some individual differences in the breakdown and absorption of methadone (Levy et al. 2000).

Fairly recently, CYP2B6 has been discovered as playing a prominent role in methadone metabolism (Gerber 2002; Gerber et al. 2004; Kharasch et al. 2004a, Rotger et al. 2005), and especially but not exclusively metabolism of the inactive S-enantiomer (Crettol et al. 2005, in press; Totah et al. 2004). Effects of CYP2B6 were demonstrated in laboratory experiments and also helped account for certain otherwise unexplained methadone-drug interactions during human trials. At present, relatively few agents have been identified as inducers or inhibitors of CYP2B6 (Faucette et al. 2004; Flockhart 2005), and there also can be individual differences in activity of this enzyme (Kharasch et al. 2004a; Rotger et al. 2005). However, as research continues, many agents currently thought to be interacting with methadone primarily via other P450 enzymes also may be identified as CYP2B6 substrates, inducers, or inhibitors. Therefore, in many cases, the most that can be stated with certainty at present is that CYP450 enzymes are involved in a methadone-drug interaction, without always knowing the relative roles of exact enzymes (personal communication, E. Kharasch, October 2005).

Another metabolic protein of some importance is P-glycoprotein (P-gp), which is found in the intestine, along the blood-brain barrier, and in other tissues (Matheny et al. 2001, Wang et al. 2004). This substance functions as a pump, transporting methadone out of cells lining the intestinal wall and back into the lumen. Thus, some of the methadone absorbed by the intestine is pumped back out before it ever enters the circulation. There is up to a 10-fold variation in the amount of intestinal P-gp expressed by individuals (Hall et al. 1999, Leavitt et al. 2000), and some interactions originally considered solely due to intestinal CYP3A4 may involve P-gp as well (Dresser et al. 2000; Eap et al. 2002; Kharasch et al. 2004b). Some evidence suggests that expression of P-gp in the blood-brain barrier, which can vary across individuals, may play a role in the access and effects of methadone in the brain and the potential for adverse effects (Wang et al. 2004). Although, one clinical study found that P-gp may not be a significant factor in this regard (Kharasch et al. 2004b).
Drugs or other agents that **induce** the activity of enzymes involved in methadone metabolism can accelerate its breakdown, increase its rate of clearance, abbreviate the duration of methadone’s effects, lower the serum methadone level (SML), and possibly precipitate an abstinence (withdrawal) syndrome. Conversely, CYP-enzyme **inhibitors** may slow methadone metabolism, raise the SML, extend the duration of its effects, and possibly cause methadone-related toxicity such as oversedation and/or respiratory depression (Eap et al. 2002; Leavitt et al. 2000; Methadose PI 2000; Payte et al. 2003; Wolff et al. 2000).

Genetic factors also can act on certain enzymes to affect methadone metabolism. For example, CYP2D6 is entirely absent in a significant portion of the population (1 out of 15 persons), resulting in increased sensitivity to methadone’s effects; conversely, some persons have high activity of this enzyme and are rapid metabolizers of methadone (Eap et al. 2002).

The variability of CYP-enzyme presence and activity means that SMLs can differ significantly even in the absence of interacting substances; some persons can naturally be either extensive (rapid) or poor (slow) metabolizers of methadone. When interactions with other drugs occur on top of this it could further influence problematic methadone under- or overmedication (Eap et al. 2002; Leavitt et al. 2000; Richelson 1997).

**Methadone-Drug Interactions**

When co-prescribing medications with methadone, and a suspected drug interaction occurs, the time course of sign/symptom development can be a guide as to whether enzyme induction or inhibition is involved. **Overmedication** reactions are likely due to CYP inhibition that develops quickly; within a few days after concurrent drug administration. In contrast, CYP induction is slower to emerge, commonly taking about a week to produce significant withdrawal signs/symptoms (Antoniou and Tseng 2002; Faragon and Piliero 2003; Gourevitch and Friedland 2000; Hansten 1995; Wolff et al. 2000). In the presence of strong CYP inducers, merely increasing the methadone dose may be insufficient and an increase plus splitting into 2 or more daily doses may be necessary.

Potential effects on methadone metabolism also should be considered when **discontinuing** medications. If a drug that inhibits CYP enzymes is stopped, methadone serum levels may decrease and cause opioid withdrawal that requires increased methadone dose. Conversely, if a CYP inducer is discontinued, metabolizing-enzyme levels will diminish and SMLs may rise to toxic levels unless careful methadone dose reductions are implemented in response to clinical signs of overmedication.

Some methadone-drug interactions primarily relate to how certain drug combinations may adversely affect physiological response in the patient (pharmacodynamics) and have little to do with altered drug metabolism. For example, the **additive effects** of methadone combined with other central nervous system (CNS) depressants may cause hypotension, sedation, respiratory depression, or coma (Leavitt 2003; Methadose PI 2000). Also, polysubstance abuse in MMT patients may put them at greater risk of adverse additive interactions with other drugs (Antonio and Tseng 2002; Harrington et al. 1999; Quinn et al. 1997).
Another concern involves the recognition of methadone’s potential to affect heart rhythm under certain circumstances (Leavitt and Krantz 2003). Researchers have reported relatively small but statistically significant QT interval increases among MMT patients, although the QT measurements generally remained within acceptable limits (Maremmani et al. 2005; Martell et al. 2005). Often, these heart rhythm changes were in patients taking medications or drugs in addition to methadone, or having cardiac risk factors that might normally be of concern (Leavitt and Krantz 2003).

In the largest retrospective investigation to date, researchers examined all adverse events associated with methadone officially reported to the FDA during a 33 year period (Pearson and Woosley 2005). Of 5,503 incidents, only 16 noted QT interval prolongation and 43 indicated torsade de pointes (TdP). Most cases involved methadone used in pain management – at doses ranging from 29 to 1,680 mg/day – and it could not be determined that methadone was a direct cause. Five cases (0.09%) were fatal; however, 3 of those involved pre-existing factors known to influence arrhythmia.

The conclusions and recommendations of all major investigations to date concur that the risk of TdP is likely to be small, should not deter caregivers or patients from methadone treatment, and it is premature to suggest routine ECGs before or during MMT. However, it would be advisable to take careful medical histories screening for known cardiac risk factors and it would be prudent not to co-prescribe methadone with other drugs known to prolong the QT interval because of the potential for additive effects (Krook et al. 2004; Leavitt and Krantz 2003; Maremmani et al. 2005; Martell et al. 2005; Pearson and Woosley 2005; Piquet et al. 2004). Thus, comedications that might produce acute elevations of serum methadone concentrations or may in themselves contribute to dysrhythmias should be used only after considering the risks versus benefits.

In cases of MMT patients on elaborate drug regimens – such as multidrug therapies for HIV/AIDS, hepatitis, and/or severe mental illness – outside consultation with specialists in such pharmacotherapies might be advised. For example, many drugs used for HIV/AIDS therapy interact with each other (Chrisman 2003; Schütz 2002) and their combined effects on methadone can be complex (Antoniou and Tseng 2002; Faragon and Piliero 2003).

**Putting Concepts Into Practice**

Methadone works best when administered in *adequate* therapeutic doses (Leavitt 2003). However, given the individual variability in methadone absorption and metabolism, it becomes difficult to accurately predict the effects of drug combinations in any one patient (Harrington et al. 1999), or how methadone dosing may need adjustment to compensate for metabolic inducers or inhibitors (Wolff et al. 2000). If a patient is responding unexpectedly or unfavorably to methadone – with signs/symptoms of under- or overmedication – a search for potentially interacting substances (prescribed medications, illicit drugs, OTC products, or other agents) would be appropriate. Taking a comprehensive history from the patient can be important in this search (Kramer 2000).

When prescribing comedications the potential for certain drugs and drug combinations to interact with methadone requires careful consideration. Furthermore, polysubstance abuse may place patients...
at risk for hazardous interactions of methadone with other opioids and drugs such as alcohol, cocaine, barbiturates, and benzodiazepines. Clinical experience, intuition, and common sense can be valuable tools for MMT practitioners in taming drug interactions and the following Table lists some suggestions.

**Clinical Suggestions for Minimizing Methadone-Drug Interactions**

1. Develop a working knowledge of methadone-drug interactions. Methadone is metabolized by multiple CYP450 enzymes. The metabolic requirements of other medications can be checked in manufacturers’ literature or standard references.

2. Just because certain drugs can interact does not mean that they will, or indicate to what extent.

3. Maintain an accurate, updated profile for each patient that includes all prescribed and illicit drugs, and OTC products (including herbal remedies and dietary supplements).

4. Use alternative, non-interacting, drugs whenever possible.

   *Usually, there are differences in the interactive properties of at least some members of any drug class. For example, the macrolide antibiotic erythromycin is a strong CYP3A4 inhibitor, likely to possibly interact with methadone, whereas the macrolide azithromycin does not appear to have this effect. Similarly, divalproex might be substituted for carbamazepine, which is a potent CYP3A4 inducer.*

5. If a potentially interacting drug is used with methadone, it is better to adjust the methadone dose based on patient response rather than in advance based on an expected interaction.

   *The magnitude of drug interactions varies dramatically from patient to patient, and it is unlikely that the selected methadone dosage adjustment would exactly offset the actual effect of the second drug.*

6. Signs/symptoms of either abstinence syndrome (withdrawal) or overmedication (sedation), and their severity, can help gauge serum methadone level (SML) adequacy in the presence of an interacting drug. Adjustments of methadone or concomitant drug(s) may be appropriate to overcome such adverse reactions.

7. If there are concerns about adverse effects of increased methadone concentrations, patients should be advised in advance of physical signs/symptoms of overmedication that might occur and what to do. It may be desirable to temporarily monitor SMLs in certain cases.

8. Whenever possible, avoid concurrent administration of drugs with overlapping adverse-effect profiles. Otherwise, signs/symptoms of major variations in methadone concentration may be confused with side effects of concomitantly administered drugs, and vice versa.

   *For example, conditions associated with impaired renal or hepatic function may significantly alter drug metabolism and excretion. Patients with preexisting cardiovascular conditions – particularly those with congestive heart failure or left ventricular systolic dysfunction – may be more sensitive to potential arrhythmogenic effects of certain drugs (including methadone).*

10. In some cases, adverse drug reactions can be resolved by prescribing a medication with or without food, by altering dosing schedules, or by splitting doses into smaller increments.

11. Unreported or seemingly inconsequential factors may play a role in drug interactions.

   *For example, grapefruit juice can hinder metabolism and increase methadone serum levels. Or, if illicit drugs are used, they may contain adulterants producing unanticipated interactions with methadone.*

12. Patients may not adhere to prescribed medication regimens, which could affect adverse reactions, and the more complicated the regimen the less likely that the patient will adhere to it. This can be important in methadone-maintained patients prescribed multiple medications.

Adapted from: Chung 2002; Cohen, 1999; Kramer 2000; Levy et al., 2000; Piscattelli and Rodvold, 2001
The traditional advice when adding drugs to a therapeutic regimen is to *start low, go slow, and monitor closely*. This may be especially prudent during MMT, since many commonly prescribed drugs are associated with dose- and concentration-dependent toxicities, and individual response may vary by several orders of magnitude. Potential adverse reactions also can be minimized by using the smallest effective doses for drugs added to methadone therapy. In many cases, doses of adjunctive medications lower than those recommended by the manufacturer may be sufficient for desired therapeutic effect (Cohen, 1999).

It has long been recognized that *patient education* is essential for successful MMT outcomes and this should be initiated early in treatment. Better informed patients can partner more effectively with clinic staff regarding their pharmaocotherapy. However, as with all other aspects of MMT, this relies on mutual trust and effective communication. Several important points need to be emphasized with patients regarding potential interactions of methadone with other substances and to help them avoid all drug interaction, as noted in the *Table* below.

### Helping Methadone Maintenance Patients Avoid Drug Interactions

- Patients maintained on methadone should be cautioned to consult healthcare professionals before taking any OTC products, herbal remedies, or dietary supplements.
- Patients should provide to their healthcare providers and pharmacist an updated list of all medical products used.
- Patients should understand their prescriptions and the dosage, and be able to cross-check what was prescribed with what they receive from the pharmacist.
- For each prescribed medication, patients should be *verbally* instructed on what the drug is used for, how to take it, and how to reduce the risk of side effects or drug interactions. It cannot be assumed that patients will read or understand product labels or written information provided with medications or other healthcare products.
- Compliance with prescribed medication regimens should be emphasized. Patients need to understand the importance of taking all medications exactly when, how, and in the quantities specified.
- Patients should be educated on the hazards of taking excess medication or sharing medicines with anyone else. They should be reminded about safe storage of medications and proper disposal of unused portions.
- Patients should be counseled on the importance of quickly reporting any sudden or unexpected signs/symptoms of either methadone withdrawal or overmedication, as this could indicate a potentially hazardous interaction with another drug or substance.
- Special consideration and instruction will be required for patients with physical conditions that may cause or exacerbate drug interactions, such as: liver or kidney disorders, pulmonary or heart ailments, pregnancy, etc.
- Patients taking multiple medications should be assisted in keeping a journal or chart listing the name, purpose, and dose schedule for each drug.
- Patients should be instructed in advance on what to do in the event of an *emergency* if their supply of methadone and/or other medications runs out and they do not have access to their usual source of supply. Ideally, such instructions also would be provided in writing.

Theoretically, any drug or substance metabolized by the same CYP enzymes as methadone, or affecting their expression by inhibition or induction, might interact with methadone; although, many of these interactions would not be clinically important. The methadone-drug interaction Tables below list only drugs and substances specifically mentioned in the scientific literature that either: A) should definitely be avoided with methadone, B) may influence unexpected results or are themselves altered by their combination with methadone, or C) raise or lower SMLs and/or increase/decrease methadone’s effects, respectively. Due to space limitations, earlier editions of this document most extensively cited literature-review articles in reporting sources of information. This current revision/update retains those references but is greatly expanded to also include citations of the primary studies and articles.

There have been a limited number of clinical studies investigating methadone interactions with specific drugs; therefore, some interactions are predicted based on lower levels of evidence, such as case reports, laboratory experiments, or pharmacologic principles. The various levels of evidence are denoted in the Tables by different colors and typefaces as follows:

- **Interaction demonstrated via published clinical studies and/or by the well-established and specific pharmacology of methadone metabolism.**
- **Based on published clinical case series reports and/or laboratory investigations in animals or tissues (in vitro).**
- **Proposed in the literature, but predicted from general pharmacologic principles and/or sporadic anecdotal cases.**

To simplify the presentation, only substances reported or proposed as interacting in a substantive way with methadone are included in the Tables. In some cases, the interaction potential of certain drugs may have been examined but no clinically significant interaction was found; therefore, these drugs are not listed in this document.

Furthermore, enzymes involved in methadone-drug interactions are often broadly indicated here as part of the CYP450 family, without specifying the exact enzymes. As noted above, this is an ongoing area of investigation and many agents currently thought to be interacting with methadone via specific P450 enzymes may be otherwise identified as time passes. Therefore, the most that often can be stated with certainty is that CYP450 enzymes are involved in a methadone-drug interaction. Clinically, this is still helpful in understanding the possible interaction and suggesting when therapeutic adjustments of methadone and/or the interacting agent(s) might be appropriate.
Finding Drugs/Substances of Interest or Concern in this Document

While viewing this Adobe Reader® PDF document, use the “Search” function to easily and quickly locate a drug/substance within the document. Click on the “Search” button icon (graphic at left) below the menu bar. This function also is available under the “Edit” menu, or by pressing the “Control [Ctrl]” plus the “F” keys simultaneously on the keyboard.

In the panel that appears along the right side of the document (graphic at right), enter the name of the drug or substance of interest or concern and click on the search button. All instances of the named drug/substance in the document will be listed and these can be selected individually for viewing.

*Note: All navigation links in this document are active for easily moving from one section to another or to additional sources of information on the Internet.*
Table Legend

**Abbreviations:** NNRTI = non-nucleoside reverse transcriptase inhibitor; NRTI = nucleoside reverse transcriptase inhibitor; PI = protease inhibitor; SML = serum methadone level; SSRI = selective serotonin reuptake inhibitor; TCA = tricyclic antidepressant.

Denotes drugs that have been associated in the literature with cardiac rhythm disturbances (prolonged QTc interval and/or torsade de pointes [TdP]) and should be used cautiously with methadone. For regularly updated information on TdP risk, see: [http://QTdrugs.org](http://QTdrugs.org) (Woosley 2003). Also see, Leavitt and Krantz 2003.

**Reference Sources:** The original document (2004) principally cited current review articles specifically mentioning methadone-drug interactions. This revision/update (2005) now also includes references to primary studies, if available, demonstrating the methadone-drug interaction.

**Note:** Drug brand names are registered trademarks of their respective manufacturers. Additional brands may be on the market and the tables may not be all-inclusive of drugs/brands that might be contraindicated or interact with methadone. Clinical experiences with drugs may differ, as there are often individual patient variations in methadone metabolism and reactions to any drug or combination of therapies.

**Levels of Evidence** (The following colors/typefaces are used in the tables to designate the certainty of interactions):

- Interaction demonstrated via published clinical studies and/or by the specific pharmacology of methadone.
- Based on published case series reports and/or laboratory investigations in animals or tissues (in vitro).
- Proposed in the literature, but predicted from general pharmacologic principles and/or sporadic anecdotal cases.

<td>Insomn-eze, Mepergan, Phenergan, others</td>
<td>Antihistamine.</td>
<td>Increased methadone effect mentioned only anecdotally, possibly due to CYP2D6 inhibition (Brown and Griffiths 2000) or synergistic sedation (Phenergan PI 2000). Effects with other phenothiazines (Thorazine, Stelazine) not reported.</td>
</tr>
<tr>
<td>stavudine (d4T)</td>
<td>Zerit</td>
<td>NRTI antiretroviral.</td>
<td>Decrease in d4T concentration; no effect on methadone (Rainey et al. 2000). Clinical significance in d4T decrease unclear; no dosage adjustments necessary.</td>
</tr>
<tr>
<td><strong>TCAs</strong></td>
<td>Elavil, Norpramin, Tofranil, Pamol, Trimipramine, Sinequan, Vivactil, and other brands</td>
<td>Tricyclic antidepressants (TCAs).</td>
<td>Combination with methadone increases TCA toxicity (DeMaria 2003; Maany et al. 1989; Quinn et al. 1997; Richelson 1997). Mixed reports of methadone increase or decrease (Eap et al. 2002; Moolchan et al. 2001; Strang 1999; Venkatakrishnan et al. 1998). Caution might be advised when using the drugs in combination with methadone due to possible proarrhythmic effects.</td>
</tr>

</table>
### Table 2 CONTINUED: Drugs That Result in Altered Metabolism / Unpredictable Interactions

<table>
<thead>
<tr>
<th>Drug</th>
<th>Description</th>
<th>Interaction Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>zidovudine (AZT)</td>
<td>Retrovir, AZT combinations (e.g., Combivir, Trizivir)</td>
<td>NRTI antiretroviral. AZT concentration increased significantly with methadone; more frequent AZT side effects are possible, but no effect on methadone (McCance-Katz et al. 1998, 2001; Rainey et al. 2002; Retrovir PI 2001; Schwartz et al. 1992; Trepnell et al. 1998).</td>
</tr>
</tbody>
</table>

### Table 3

**Drugs That May LOWER SML and/or DECREASE Methadone Effects**

<table>
<thead>
<tr>
<th>Generic Name(s)</th>
<th>Brands/Examples</th>
<th>Actions/Uses</th>
<th>Notes/References</th>
</tr>
</thead>
<tbody>
<tr>
<td>abacavir (ABC)</td>
<td>Ziagen</td>
<td>NRTI antiretroviral. Methadone level mildly decreased; also reduces ABC peak concentration (Bart et al. 2001; Gourevitch 2001; Sellers et al. 1999; Ziagen PI 2002).</td>
<td></td>
</tr>
<tr>
<td>amprenavir</td>
<td>Agenerase</td>
<td>PI antiretroviral. CYP3A4 enzyme induction may decrease methadone levels (Agenerase PI 1999; Bart et al. 2001; Chrisman 2003; Eap et al. 2002), but no adjustment in methadone dose required (Henrix et al. 2000, 2004). Amprenavir levels also may be reduced but the clinical significance is unclear.</td>
<td></td>
</tr>
<tr>
<td>barbiturates</td>
<td>Amytal, Butisol, Fioricet, Fiorinal, Lotusate, Luminal, Mebaral, Nемbutal, Pheno-barbital, Seconal, Talbutal, Tuinal, and others</td>
<td>Barbiturate sedatives and/or hypnotics. CYP450 enzyme induction (Kreek 1986). Phenobarbital, the most studied, can cause sharp decrease in methadone (Alvares and Kappas 1972; Faucette et al. 2004; Gourevitch 2001; Liu and Wang 1984; Plummer et al. 1988) A methadone dose increase may be required.</td>
<td></td>
</tr>
<tr>
<td>cocaine♥</td>
<td>Crack, coke, others</td>
<td>Illicit stimulant. Accelerates methadone elimination (Moolchan et al. 2001).</td>
<td></td>
</tr>
<tr>
<td>dexamethasone</td>
<td>Decadron, Hexadrol</td>
<td>Corticosteroid. CYP3A4 and CYP2B6 enzyme inducer (Eap et al. 2002; Faucette et al. 2004); cases reported in pain patients (Plummer et al. 1988).</td>
<td></td>
</tr>
<tr>
<td>efavirenz</td>
<td>Sustiva</td>
<td>NNRTI antiretroviral. Due to CYP3A4 and/or CYP2B6 induction (Barry et al. 1999; Boiffito et al. 2002; Clarke et al. 2000, 2001a; Eap et al. 2002, Gerber et al. 2004; Marzolini et al. 2000; McCance-Katz et al. 2002; Pinzanni et al. 2000; Rotger et al. 2005; Tashima et al. 1999). Methadone withdrawal is common and a significant methadone dose increase is usually required.</td>
<td></td>
</tr>
<tr>
<td>ethanol (chronic use)</td>
<td>Wine, beer, whiskey, etc.</td>
<td>Euphoric, sedative. CYP450 enzyme induction (Borowsky and Lieber 1978; Kreek 1976, 1984; Quinn et al. 1997).</td>
<td></td>
</tr>
<tr>
<td>fusidic acid</td>
<td>Fucidin</td>
<td>Steroidal antibacterial. CYP450 enzyme induction (Eap et al. 2002; Van Beusekom and Iguchi 2001); reports of opioid withdrawal symptoms after 4-weeks of therapy (Reimann et al. 1999).</td>
<td></td>
</tr>
<tr>
<td>heroin</td>
<td>Smack, scat, others</td>
<td>Illicit opioid. Decreases free fraction of methadone (Moolchan et al. 2001).</td>
<td></td>
</tr>
<tr>
<td>Drug Combination</td>
<td>Brand Name(s)</td>
<td>Category</td>
<td>Effect on Methadone</td>
</tr>
<tr>
<td>------------------</td>
<td>--------------</td>
<td>----------</td>
<td>---------------------</td>
</tr>
<tr>
<td>lopinavir + ritonavir</td>
<td>Kaletra</td>
<td>PI antiretroviral.</td>
<td>Combination lowers SML (Clarke et al. 2002), although there is some evidence to the contrary (Stevens et al. 2003). Withdrawal symptoms might occur requiring methadone dose increase; however, side effects of Kaletra may mimic GI side effects of opioid withdrawal. Most but not all research suggests this effect is not seen with ritonavir alone or ritonavir/saquinavir combination (Beauverie et al. 1998; Chrisman 2003; Geletko and Erickson 2000; Gerber et al. 2001; Hsu et al. 1998; Kharasch and Hoffer 2004; McCance-Katz et al. 2003; Munsiff et al. 2001; Shelton et al. 2001, 2004) although ritonavir induces CYP 2B6 (Faucette et al. 2004).</td>
</tr>
<tr>
<td>nefinavir</td>
<td>Viracept</td>
<td>PI antiretroviral.</td>
<td>CYP3A4 and P-gp induction (Beauverie et al. 1998; Eap et al. 2002), but clinical methadone withdrawal is rare (Brown et al. 2001; Hsyu et al. 2000; Maroldo et al. 2000; McCance-Katz et al. 2004); however, manufacturer suggests methadone may need to be increased (Viracept PI 2000). Interaction may (Chrisman 2003) or may not (McCance-Katz et al. 2004) occur to decrease nefinavir, which also is a potent inhibitor of CYP2B6 (Antoniou and Tseng 2002).</td>
</tr>
<tr>
<td>nevirapine</td>
<td>Viramune</td>
<td>NNRTI antiretroviral.</td>
<td>CYP3A4 and/or 2B6 enzyme induction reduces methadone level and precipitates opioid withdrawal. Methadone dose increase necessary in some patients (Altice et al. 1999; Clarke et al. 2001; Eap et al. 2002; Gerber et al.; Heelon et al. 1999; Otero et al. 1999; Pinzanni et al. 2000; Rotger et al. 2005; Staszewski et al. 1998).</td>
</tr>
<tr>
<td>spironolactone</td>
<td>Aldactone</td>
<td>K⁺-sparing diuretic.</td>
<td>Possible CYP450 induction (Eap et al. 2002). Effect observed in patients receiving methadone for cancer pain (Plummer et al.).</td>
</tr>
<tr>
<td>St. John’s wort (Hypericum perforatum)</td>
<td>Ingredient in various OTC products</td>
<td>Herb used as antidepressant.</td>
<td>Induces CYP3A4 and P-gp; 47% decrease in methadone noted in one study (Eich-Höchli et al. 2003; Scot and Elmer 2002).</td>
</tr>
<tr>
<td>tobacco</td>
<td>Various brands</td>
<td>Habitual smoking.</td>
<td>Some mixed reports, but most indicate reduced effectiveness of methadone, possibly due to CYP1A2 induction (Eap et al. 2002; Moolchan et al. 2001; Tacke et al. 2001).</td>
</tr>
<tr>
<td>urinary acidifiers (e.g., ascorbic acid)</td>
<td>Vitamin C (extremely large doses); K-Phos</td>
<td>Dietary supplement; keeps calcium soluble.</td>
<td>Proposed, methadone excreted by kidneys more rapidly at lower pH (Nillson et al. 1982; Strang 1999).</td>
</tr>
</tbody>
</table>

### Table 4

**Drugs That May RAISE SML and/or INCREASE Methadone Effects**

**Warning:** Acute increases in serum methadone concentration may produce significant signs/symptoms of methadone overmedication, possibly resulting in overdose. Recent data suggest that in susceptible individuals acutely elevated methadone levels – alone or, more commonly, in combination with other drugs and/or cardiac risk factors – may influence cardiac rhythm disturbances (prolonged QTc interval and/or torsade de pointes; see Leavitt and Krantz 2003).

<tr>
<td>amiodarone♥, diltiazem</td>
<td>Cordarone, Cardizem, Diltia, Tiazac, Cardioquin, Quinaglute, Dura-Tabs, others</td>
<td>Heart rhythm stabilizers, antihypertensives.</td>
<td>Recently proposed in the literature (Vlessides 2005) possibly due to CYP450 inhibition (Flockhart 2005), but not otherwise verified.</td>
</tr>
<tr>
<td>cimetidine</td>
<td>Tagamet</td>
<td>H₂-receptor antagonist for GI disorders.</td>
<td>CYP450 enzyme inhibitor (Bochner 2000; Dawson and Vestal 1984; Sorkin and Ogawa 1983; Strang 1999).</td>
</tr>
<tr>
<td>ciprofloxacin</td>
<td>Cipro</td>
<td>Quinolone antibiotic.</td>
<td>Inhibition of select CYP450 enzymes (Eap et al. 2002; Herlin et al. 2000).</td>
</tr>
<tr>
<td>delavirdine</td>
<td>Rescriptor</td>
<td>NNRTI antiretroviral.</td>
<td>Predicted effect due to CYP450 enzyme inhibition (Gourevitch 2001; McCance-Katz et al. 2004, 2005); manufacturer suggests methadone dose may need to be decreased (Rescriptor PI 2001).</td>
</tr>
<tr>
<td>dihydroergotamine</td>
<td>D.H.E., Migranal</td>
<td>Migraine treatment.</td>
<td>Predicted due to CYP3A4 enzyme inhibition (Van Beusekom and Iguchi 2001).</td>
</tr>
<tr>
<td>disulfiram</td>
<td>Antabuse</td>
<td>Alcoholism treatment.</td>
<td>Sedation in MMT patients noted with higher doses of disulfiram (Bochner 2000), but some reports inconclusive (Tong et al. 1980).</td>
</tr>
<tr>
<td>fluconazole</td>
<td>Diflucan</td>
<td>Anti-fungal antibiotic.</td>
<td>CYP450 enzyme inhibition (Eap et al. 2002); increased methadone levels (Cobb et al. 1998; Gourevitch 2001); clinical significance uncertain (Levy et al. 2000, Tamuri et al. 2002). Other azole antifungals may potentially influence opioid toxicity: e.g., itraconazole, ketoconazole♥, voriconazole.</td>
</tr>
<tr>
<td>grapefruit juice or whole fruit</td>
<td>Food.</td>
<td></td>
<td>Inhibits intestinal CYP3A4 (Bailey et al. 1998; Dresser et al. 2000; Hall et al. 1999) and P-gp (Benneburek et al. 2004; Dresser et al. 2000; Eagling et al. 1999; Eap et al. 2002); although, there is some conflicting evidence (Kharasch et al. 2004). This effect is not expected with other fruits/juices (Karlix 1990).</td>
</tr>

### Table 5

#### Methadone-Drug Interactions

**Alphabetical Listing by Generic & Brand Names**

**NOTE:** Drug *Brand Names* begin with capital letters and are registered trademarks of their respective manufacturers. All others are generic agents.

The listings here may not be all-inclusive of drugs/brands that might be contraindicated or interact with methadone. Furthermore, clinical experiences with medications may differ, as there are often individual variations in methadone metabolism and reactions to any drug, substance, or combination of therapies.

Interactions resulting in acute SML increases are of special concern, since they may produce signs/symptoms of overmedication and possible overdose. In individuals with cardiac risk factors, methadone’s combination with other drugs having arrhythmogenic potential may influence cardiac rhythm disturbances.

**Symbols:**
- ⚠️ = contraindicated with methadone (may cause opioid withdrawal, possibly severe).
- ⚠️ = may result in altered metabolism or unpredictable interactions with methadone.
- ↑ = increases serum methadone level (SML) and/or increases methadone effects.
- ↓ = decreases serum methadone level (SML) and/or decreases methadone effects.
- ♥ = drug has been associated with cardiac rhythm disturbances (prolonged QTc interval and/or torsade de pointes) and should be used cautiously with methadone. For latest listings see: [http://Qtdrugs.org](http://Qtdrugs.org).

**Levels of Evidence** (The following colors/typefaces are used in the tables to designate the certainty of interactions):
- ■ Interaction demonstrated via published clinical studies and/or by the specific pharmacology of methadone.
- □ Based on case series reports and/or laboratory investigations in animals or tissues (in vitro).
- □ Proposed in the literature, but predicted from general pharmacologic principles and/or sporadic anecdotal cases.

</table>
dezocine ✨ Displaces methadone on μ-opioid receptors.
diazepam ↑ Effect sporadic, unknown mechanism.
didanosine (ddl buffered tab) ↓ Decrease in ddl (effect not seen with enteric-coated).

Diflucan ↑ CYP3A4 inhibition. Case reports requiring dose reduction reported.

dihydroergotamine ↑ CYP450 enzyme inhibition.

dilantin ↓ Sharp decrease, CYP3A4 induction.
Diltia ↑ Proposed due to CYP450 inhibition.
diltiazem ↑ Proposed due to CYP450 inhibition.
Distraneurin ✨ Enhanced sedative effects.
disulfiram ↑ Sedation reported.
Dizac ↑ Effect sporadic, unknown mechanism.
doxepin ♥ ✨ Possible increased TCA toxicity; uncertain effect on methadone.

Duramorph ✨ Common CYP450 pathway; possible additive effects with methadone.

Dura-Tabs ↑ Proposed due to CYP450 inhibition.
E.E.S., Eryped ♥ ↑ Strong CYP3A4 inhibition.
Echinacea ↑ Predicted due to CYP450 inhibition.
Emoquil ✨ Increased sedative effects if abused.
efavirenz ↓ Due to CYP3A4/2B6 induction, methadone withdrawal common.

Elavil ♥ ✨ Possible increased TCA toxicity; uncertain effect on methadone.

erythromycin ♥ ↑ Strong CYP3A4 inhibition.

erythromycin ♥ ↑ Strong CYP3A4 inhibition.

Eryzole ♥ ↑ Strong CYP3A4 inhibition.
estazolam ✨ Potential interaction, additive CNS depression.

fluconazole ↑ CYP3A4 inhibition. Case reports requiring dose reduction reported.

fluoxetine ♥ ↑ Variable CYP450 enzyme inhibition.
flurazepam ✨ Potential interaction, additive CNS depression.
fluvaxamine ↑ Variable CYP450 enzyme inhibition.

Fucidin ↓ CYP450 induction.
fusidic acid (systemic) ↓ CYP450 induction.
Goldenseal ↑ Proposed due to CYP3A4 inhibition but unverified.

Grapefruit ↑ Inhibition of intestinal CYP3A4 and P-gp.

Halcion ✨ Potential interaction, additive CNS depression.
hash ✨ Proposed interaction, common CYP450 pathway.
hemp ✨ Proposed interaction, common CYP450 pathway.
Hemineurin ✨ Enhanced sedative effects.
Heminevrin ✨ Enhanced sedative effects.
heroine ↓ Decreases methadone free fraction.
Hexadrol ↓ CYP3A4 induction.
hydrastis canadensis ↑ Predicted due to CYP3A4 inhibition.

Hydrocodone ✨ Common CYP450 pathway; possible additive effects with methadone.

Hypericum perforatum ↓ Significant decrease; CYP3A4 and P-gp induction.
illosone ♥ ↑ Strong CYP3A4 inhibition.
Methadone-Drug Interactions

imipramine ♥ Possible increased TCA toxicity; uncertain effect on methadone.
Imovane ♥ Potential interaction, additive CNS depression.
Insom-n-eze ♥ Possible increased sedation or methadone effects.
interferon-alfa + ribavirin ♥ Side effects may mimic opioid withdrawal.
Isoptin ↑ Predicted due to CYP450 inhibition.
Kaletra ↓ Effect not seen with ritonavir alone.
ketocanazole ♥ ↑ Predicted due to CYP3A4 inhibition.
K-Phos ↓ Proposed due to more rapid urinary excretion.
liparin + ritonavir ↓ Effect not seen with ritonavir alone.
Lotusate ↓ Due to CYP450 enzyme induction.
Luminal ↓ Possibly sharp decrease in methadone.
Luvox ↑ Variable CYP450 enzyme inhibition.
macrolide antibiotics ↑ CYP3A4 inhibition (not azithromycin).
Manerix ↑ Possible due to CYP450 inhibition.
MAO (monoamine oxidase) inhibitors
Mareine (Marzine) ♥ Increased sedative effects if abused.
marijuana ♥ Proposed interaction, common CYP450 pathway.
matticaria recutita ↑ Predicted due to CYP3A4 inhibition.
Mebaral ↓ Due to CYP450 enzyme induction.
meclizine ↓ Increased sedative effects if abused.
Mepergan ♥ Possible increased sedation or methadone effects.
meperidine ♥ Possible opioid additive effects; long-acting toxic metabolites.
methylenidate ↓ Due to CYP450 enzyme induction.
methiodizole ↑ Proposed due to CYP3A4 inhibition but unverified.
midazolam ↓ Potential interaction, additive CNS depression.
Migranal ↑ Possible CYP450 enzyme inhibition.
mocloboemide ↑ Possible due to CYP450 inhibition.
morphine ♥ Common CYP450 pathway; possible additive effects with methadone.
MS Contin ♥ Common CYP450 pathway; possible additive effects with methadone.
Myidone ↓ CYP450 induction proposed.
Mysoline ↓ CYP450 induction proposed.
nalbuphine ⊙ Displaces methadone on µ-opioid receptors.
nalmefene ⊙ Displaces methadone on µ-opioid receptors.
naloxone ⊙ Displaces methadone on µ-opioid receptors.
naltrexone ⊙ Displaces methadone on µ-opioid receptors.
Narcan ⊙ Displaces methadone on µ-opioid receptors.
Nardil ⊙ Potential adverse interaction.
nefazodone ↑ Variable CYP450 enzyme inhibition.
nelfinavir ↓ Possible decrease also in nelfinavir; methadone increase rarely needed.
Nembutal ↓ Due to CYP450 enzyme induction.
nevirapine ↓ Frequent opioid withdrawal syndrome.
nifedipine ♥ Nifedipine increase proposed.
Nizoral ♥ ↑ Predicted due to CYP450 inhibition.
Noctec ♥ Additive effects, possibly fatal.
Norpramin ♥ ♥ Possible increased TCA toxicity; uncertain effect on methadone.
nortriptyline ♥ ♥ Possible increased TCA toxicity; uncertain effect on methadone.
Nubain ⊙ Displaces methadone on µ-opioid receptors.
omeprazole  
  Possibly affects methadone absorption.

opioid analgesics  
  Common CYP450 pathway; possible additive effects with methadone.

oxycodone  
  Common CYP450 pathway; possible additive effects with methadone.

OxyContin  
  Common CYP450 pathway; possible additive effects with methadone.

Pamelor  
  Possible increased TCA toxicity; uncertain effect on methadone.

Parnate  
  Potential adverse interaction.

paroxetine  
  Variable CYP450 enzyme inhibition.

Paxil  
  Variable CYP450 enzyme inhibition.

Pegasys  
  Side effects may mimic opioid withdrawal.

pentazocine  
  Displaces methadone on µ-opioid receptors.

pentobarbital  
  Due to CYP450 enzyme induction.

Phenergan  
  Proposed interaction, common CYP450 pathway.

phenobarbital  
  Sharp decrease, CYP3A4 induction.

Polycitra  
  Decreases methadone urinary excretion.

pot (marijuana)  
  Proposed interaction, common CYP450 pathway.

Prevpac  
  CYP3A4 inhibition (contains clarithromycin).

Prilosec  
  Possibly affects methadone absorption.

primidone  
  CYP450 induction proposed.

Procardia  
  Nifedipine increase proposed.

propranolol  
  Possible increased TCA toxicity; uncertain effect on methadone.

Prozac  
  Variable CYP450 enzyme inhibition.

quercetin  
  Proposed due to CYP450 inhibition.

Quinaglute  
  Proposed due to CYP450 inhibition.

quinine  
  Proposed due to CYP450 inhibition.

Rebetron  
  Side effects may mimic opioid withdrawal.

Rescriptor  
  Due to CYP450 inhibition.

Retrovir  
  AZT concentration and related side effects increased.

Revex  
  Displaces methadone on µ-opioid receptors.

ReVia  
  Displaces methadone on µ-opioid receptors.

ribavirin + interferon-alfa  
  Side effects may mimic opioid withdrawal.

Rifadin  
  Possibly severe; CYP450 induction.

Rifamate  
  Possibly severe; CYP450 induction (not seen with rifabutin).

rifampicin  
  Possibly severe; CYP450 induction (not seen with rifabutin).

rifampin  
  Possibly severe; CYP450 induction (not seen with rifabutin).

rifampin/isoniazid  
  Possibly severe; CYP450 induction (not seen with rifabutin).

Rimactane  
  Possibly severe; CYP450 induction (not seen with rifabutin).

Ritalin, Ritalin SR  
  CYP450 inhibition.

ritonavir + lopinavir  
  Effect not seen with ritonavir alone.

Robitussin  
  Increased dextromethorphan effects proposed.

scat (heroin)  
  Decreases methadone free fraction.

secobarbital  
  Due to CYP450 enzyme induction.

Seconal  
  Due to CYP450 enzyme induction.

sertraline  
  Variable CYP450 enzyme inhibition.

Serzone  
  Variable CYP450 enzyme inhibition.

<td>✡</td>
<td>Decrease in ddl (effect not seen with enteric-coated).</td>
</tr>
<tr>
<td><strong>Viracept</strong></td>
<td>↓</td>
<td>Possible decrease also in Viracept.</td>
</tr>
<tr>
<td><strong>Viramune</strong></td>
<td>↓</td>
<td>Frequent opioid withdrawal syndrome.</td>
</tr>
<tr>
<td><strong>vitamin C (very high dose)</strong></td>
<td>↓</td>
<td>Proposed due to more rapid urinary excretion.</td>
</tr>
<tr>
<td><strong>Vivactil</strong></td>
<td>✡</td>
<td>Possible increased TCA toxicity; uncertain effect on methadone.</td>
</tr>
</tbody>
</table>
wine, beer, whiskey (acute use)  
Competition for CYP450 enzymes.

wine, beer, whiskey (chronic use)  
CYP450 enzyme induction.

Xanax  
Potential interaction, additive CNS depression.

zafirlukast  
Proposed due to CYP450 inhibition.

Zerit (d4T)  
Decreased d4T concentration (unclear clinical significance).

Ziagen  
Also decreases Ziagen peak concentration

zidovudine (AZT)  
AZT concentration increased and side effects common.

zileuton  
Proposed due to CYP450 inhibition.

Zoloft  
Variable CYP450 enzyme inhibition.

zopiclone  
Potential interaction, additive CNS depression.

Zyflo  
Proposed due to CYP450 inhibition.
